Determining the Creep Compliance and Strength of Hot Mix Asphalt (HMA) Using the Indirect Tensile Test Device

AASHTO Designation: T 322-07 (2020)

AASHO

Technical Subcommittee: 2d, Proportioning of Asphalt–Aggregate Mixtures

Release: Group 3 (July)

CODE

A

1.	JUUPE
1.1.	This standard provides procedures for determining the tensile creep compliance at different loading times, tensile strength, and Poisson's ratio of hot mix asphalt (HMA) using indirect loading techniques.
1.2.	The procedures described in this standard provide the data required to conduct the thermal cracking analysis. These procedures apply to test specimens having a maximum aggregate size of 38 mm or less. Specimens shall be 38 to 50 mm high and 150 ± 9 mm in diameter.
1.3.	This test may involve hazardous materials, operations, and equipment. This standard does not

1.3. This test may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. REFERENCED DOCUMENTS

2.2. *ASTM Standards*:

- D3549/D3549M, Standard Test Method for Thickness or Height of Compacted Bituminous Paving Mixture Specimens
- D4123, Standard Test Method for Indirect Tension Test for Resilient Modulus of Bituminous Mixtures (withdrawn 2003; no replacement)

 D5361/D5361M, Standard Practice for Sampling Compacted Asphalt Mixtures for Laboratory Testing

3. TERMINOLOGY

- 3.1. *Definitions*:
- 3.1.1. *creep*—the time-dependent part of strain resulting from stress.
- 3.1.2. *creep compliance*—the time-dependent strain divided by the applied stress.
- 3.1.3. *tensile strength*—the strength shown by a specimen subjected to tension, as distinct from torsion, compression, or shear.
- 3.1.4. *Poisson's ratio* (v)—the absolute value of the ratio of transverse strain to the corresponding axial strain resulting from uniformly distributed axial stress below the proportional limit of the material.

4. SUMMARY OF METHOD

- 4.1. This standard describes the procedure for determining the tensile creep and tensile strength to be determined on the same specimen for thermal cracking analyses.
- 4.2. The tensile creep is determined by applying a static load of fixed magnitude along the diametral axis of a specimen. The horizontal and vertical deformations measured near the center of the specimen are used to calculate a tensile creep compliance as a function of time. Loads are selected to keep horizontal strains in the linear viscoelastic range (typically below a horizontal strain of 500×10^{-6} mm/mm) during the creep test. By measuring both horizontal and vertical deformations in regions where the stresses are relatively constant and away from the localized nonlinear effects induced by the steel loading strips, Poisson's ratio can be more accurately determined. Creep compliance is sensitive to Poisson's ratio measurements.
- 4.3. The tensile strength is determined immediately after determining the tensile creep or separately by applying a constant rate of vertical deformation (or ram movement) to failure.

5. SIGNIFICANCE AND USE

- 5.1. Tensile creep and tensile strength test data are required for Superpave mixtures to determine the master relaxation modulus curve and fracture parameters. This information is used to calculate the thermal cracking of HMA. The master relaxation modulus curve controls thermal crack development, while the fracture parameter defines a mixture's resistance to fracture.
- 5.2. The values of creep compliance, tensile strength, and Poisson's ratio determined with this method can be used in linear viscoelastic analysis to calculate the low temperature thermal cracking potential of asphalt concrete.
- 5.3. Tensile creep data may be used to evaluate the relative quality of materials.
- 5.4. This procedure is applicable to newly prepared mixtures, reheated, and recompacted mixtures. Reheated and recompacted mixtures will have lower creep compliance values than newly prepared mixtures when measured under these specific loading conditions and temperatures.
- 5.5. This procedure is applicable for mixtures with a maximum aggregate size of 38 mm or less.
